

You Can Help Pollinators!

- ✓ Create new pollinator habitat by planting shrubs that have a variety of flower sizes, shapes, and colours, and that bloom at different times of the year to provide consistent food sources.
- ✓ Maintain patches of bare soil, leaf litter and decaying logs and snags for nesting sites for both ground and tunnel nesting species.
- ✓ Make a bee hotel to provide nest sites for bees that nest in cavities.

EALT protects ecologically significant land which is important habitat for many bee species as well as other pollinators. You can support EALT by volunteering or donating. Visit ealt.ca for more information.

Thank You!

Thank you to Dr. Jessamyn Manson, Monica Kohler and Ashton Sturm for their assistance in creating this guide. Funding for this project provided by the Commission for Environmental Cooperation and The Sitka Foundation.

Bee Identification Guide

Introduction

The Edmonton and Area Land Trust works to protect natural areas to benefit wildlife and people, biodiversity and all nature's values, for everyone, forever. We steward these special places with volunteers and neighbours, who are critical to our work, and we educate the public to protect nature for future generations.

On our conservation lands, it is common to see members of the Hymenoptera order. Bees, wasps, and flies are all part of this group. These incredible species are responsible for pollinating 1/3 of our food!

There are two main differences between wasps and bees:

- 1) Bees are generally hairy and wasps are less so
- 2) Bees only eat pollen and nectar, whereas wasps also eat other insects.

Only female bees have stingers, and only the stingers of honeybees are barbed.

Unlike bees, flies have only two wings. Their antennae are also much shorter than those of bees, and their eyes are bigger and closer together.

There are over 300 species of bees in Alberta. This guide includes a summary of several of the most common groups, by genus.

Apis – Honey Bees

Brought to North America from Europe, the Honey Bee is a non-native social bee known for storing honey within their nest made of wax. There are three types of honey bee: the queen, worker, and drone.

The **queen** is the largest bee in the colony. She goes on a mating flight and mates with several drones before returning to the hive. After mating, the queen can lay around 2,000 eggs per day.

Worker bees are the smallest and all are females. They do everything for the hive, from cleaning to feeding the larvae. They can live up to 45 days. When they fly from flower to flower, they 'wet' the pollen so it sticks to their legs during the flight back to the nest.

Drone bees are all males, and are the middle sized bee in the colony. Their sole job is to mate with queens from other colonies. They can live up to 90 days but die immediately after they have mated with the queen.

Andrena – Miner Bees

Nest: In ground

Identification: Medium sized and often black-brown with some red. They have facial fovea (depressions beside each eye)

Area: Worldwide

Interesting Fact: Dig tunnels in the soil to lay eggs. Sub-social and live in loose groups, but raise own young

Bombus – Bumblebees

Nest: In ground in a group

Identification: Very large bodied and fuzzy. Make a loud buzzing sound

Area: Worldwide

Interesting Fact: A colony produces multiple new queens who overwinter and establish new colonies the next year. The queen & workers of the existing colony die

Lasioglossum – Sweat Bees

Nest: In ground

Identification: Sweat bees are variable in size with many very small species. They often have a metallic body colour and weak wing venation

Area: Worldwide

Interesting Fact: Like to land on people and lick the sweat off their skin

Nomada – Cuckoo Bees

Nest: They are cleptoparasites, which means they lay eggs in another bee's nest so the other bee provides for their young

Identification: Wasp-like, distinct colouration, often red with yellow & black banding

Area: Worldwide

Interesting Fact: Do not make nests or provide for their young

Anthophora — Digger Bees

Nest: In ground

Identification: Smaller and narrower than bumblebees, and often have light coloured hair

Area: Worldwide except Australia and SE Asia

Interesting Fact: These bees do better in cool weather than other species, and are good at "shivering" to warm themselves up

Hylaeus – Masked Bees

Nest: In cavities, secrete cellophane-like substance for nests

Identification: Very small, primarily black, wasp-like bees, with yellow markings on face, shoulders and legs. Very few hairs on body

Area: Worldwide

Interesting Fact: Store pollen internally in crops (nectar stomachs) not on their bodies

Megachile – Leafcutter Bees

Nest: In cavities, using cut up leaves to build nests

Identification: Scopal hairs (pollen-collecting hairs) on bottom of abdomen, two submarginal cells (part of wing membrane) in wings, large sharp mandibles (jaw-like)

Area: Worldwide

Interesting Fact: During pollination, pollen sticks to the underside of the abdomen

Osmia – Mason Bees

Nest: In cavities, using mud to build nests

Identification: Metallic blue bees with scopal hairs (pollen-collecting hairs) on bottom of abdomen. They also have two submarginal cells (part of wing membrane) in their wings

Area: Worldwide

Interesting Fact: Females use horns on their faces to pack mud
